

14-18 June 2021

NewTimes – New Trends in Materials Science and Engineering 1st International Virtual Conference

SESSION 5: *New trends in surface science and coatings*

Invited presentation

Black Phosphorus n-type doping by Cu: a microscopic surface investigation

Stefan Heun*

NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, Piazza San Silvestro, Pisa, Italy

Black phosphorus (bP) has emerged as an interesting addition to the category of two-dimensional materials. Surface-science studies on this material are of great interest, but they are hampered by bP's high reactivity to oxygen and water, a major challenge to scanning tunneling microscopy (STM) experiments. Consequently, the large majority of these studies were performed by cleaving a bulk crystal in situ. We have developed a technique, which allows preparing clean exfoliated bP flakes for surface science studies, using epitaxial monolayer graphene as a conductive substrate for the exfoliation of the bP flakes [1].

Based on this approach, we study surface charge transfer doping of exfoliated black phosphorus flakes by copper using scanning tunneling microscopy and spectroscopy (STS) at room temperature [2]. The tunneling spectra reveal a gap in correspondence of Cu islands, which is attributed to Coulomb blockade phenomena. Moreover, using line spectroscopic measurements across small copper islands, we exploit the potential of the local investigation, showing that the n-type doping effect of copper on bP is short-ranged. These experimental results are substantiated by first-principles simulations, which quantify the role of cluster size for an effective n-type doping of bP and explain the Coulomb blockade by an electronic decoupling of the topmost bP layer from the underlying layers driven by the copper cluster. Our results provide novel understanding, difficult to retrieve by transport measurements, of the doping of bP by copper, which appears promising for the implementation of ultra-sharp p-n junctions in bP.
